jqpeng0@foxmail.com, myxiao@gamil.com

## Our contribution

- An improved parameterized algorithm for SAT running in $O^{*}\left(1.0646^{L}\right)$, where $L$ is length of the input CNF-formula.

## Our contribution

- An improved parameterized algorithm for SAT running in $O^{*}\left(1.0646^{L}\right)$, where $L$ is length of the input CNF-formula.
- Branch and Search: New branching rules.

## Our contribution

- An improved parameterized algorithm for SAT running in $O^{*}\left(1.0646^{L}\right)$, where $L$ is length of the input CNF-formula.
- Branch and Search: New branching rules.
- Measure and Conquer: Some assumptions on weights.

## Outline

(1) Problem Definition and Background
(2) Our Algorithm
(3) Analysis of Running Time Bound
(4) The Final Result

## Problem Definition

## The Satisifiability Problem

Given a CNF formula $\mathcal{F}=C_{1} \wedge \cdots \wedge C_{m}$ on $n$ boolean variables $x_{1}, \cdots, x_{n}$, decide if there is an assignment to $x_{1}, \cdots, x_{n}$ that makes $\mathcal{F}=1$.

## Problem Definition

## The Satisifiability Problem

Given a CNF formula $\mathcal{F}=C_{1} \wedge \cdots \wedge C_{m}$ on $n$ boolean variables $x_{1}, \cdots, x_{n}$, decide if there is an assignment to $x_{1}, \cdots, x_{n}$ that makes $\mathcal{F}=1$.

## Example

- $\mathcal{F}_{1}=\left(x_{1} \vee x_{2} \vee \overline{x_{3}}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{3} \vee x_{4}\right)$.

Solution: $x_{1}=1, x_{2}=0, x_{3}=1, x_{4}=1 \Rightarrow \mathcal{F}_{1}$ is satisifiable.

## Problem Definition

## The Satisifiability Problem

Given a CNF formula $\mathcal{F}=C_{1} \wedge \cdots \wedge C_{m}$ on $n$ boolean variables $x_{1}, \cdots, x_{n}$, decide if there is an assignment to $x_{1}, \cdots, x_{n}$ that makes $\mathcal{F}=1$.

## Example

- $\mathcal{F}_{1}=\left(x_{1} \vee x_{2} \vee \overline{x_{3}}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{3} \vee x_{4}\right)$.

Solution: $x_{1}=1, x_{2}=0, x_{3}=1, x_{4}=1 \Rightarrow \mathcal{F}_{1}$ is satisifiable.

- $\mathcal{F}_{2}=\left(x_{1} \vee x_{2}\right) \wedge\left(\overline{x_{1}} \vee x_{2}\right) \wedge\left(x_{1} \vee \overline{x_{2}}\right) \wedge\left(\overline{x_{1}} \vee \overline{x_{2}}\right)$.

Solution: Not exist $\Rightarrow \mathcal{F}_{2}$ is not satisifiable.

## Background

The SAT problem has been extensively and intensively studied in many fields:

- heuristic algorithms
- randomized algorithms
- approximation algorithms
- exact and parameterized algorithms
- ...

## Background

The SAT problem has been extensively and intensively studied in many fields:

- heuristic algorithms
- randomized algorithms
- approximation algorithms
- exact and parameterized algorithms
- ...

## Background

There are three popular parameters to measure the running time of algorithms for SAT:

## Parameter/Measure

$n$ : the number of variables
$m$ : the number of clauses
$L$ : the number of literals (length)

## Best Running Time Bound

 $O^{*}\left(2^{n}\right)^{1}$$O^{*}\left(1.2226^{m}\right)^{2}$ $O^{*}\left(1.0646^{L}\right)^{3}$

Strong Exponential Time Hypothesis: The SAT Problem can not be solved in time $O^{*}\left(2^{n}\right)$.

Our contribution is improving the running time bound in terms of the number of literals (formula length).

[^0]

## Our Algorithm - Overview

Our algorithm is a standard branch-and-search algorithm (Davis-Putnam-Logemann-Loveland (DPLL) algorithm):

- We first apply some reduction rules to reduce the instance.
- Reduce the size (measure) of the formula and bring us some properties
- Take polynomial time
- When no reduction rules can be applied, we will search for a solution by branching.
- Assign value(s) to variable(s) or literal(s)
- Exponentially increase the running time

## Preliminaries

- $(i, j)$-literal: a literal $z$ is called an $(i, j)$-literal in a formula $\mathcal{F}$ if $z$ appears $i$ times and $\bar{z}$ appears $j$ times in the formula $\mathcal{F}$. $\left(i^{+}, j\right)$-literal, $\left(i, j^{+}\right)$-literal, $\left(i^{+}, j^{+}\right)$-literal, $\ldots$
- Degree: For a variable $x$ in a formula $\mathcal{F}$, the degree of it, denoted by $\operatorname{deg}(x)$, is the number of times it appears in the formula. We say a variable is an $i$-variable if the degree of it is $i$.
$i^{+}$-variable, $i^{-}$-variable, ...
- Length: The length of a clause $C$, denoted by $|C|$, is the number of literals in it. We call a clause $k$-clause if the length of it is $k$. $k^{+}$-clause, ...

$$
\begin{gathered}
\mathcal{F}=\left(x_{1} \vee x_{2} \vee \overline{x_{3}}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{3} \vee x_{4}\right) \wedge\left(\overline{x_{1}} \vee x_{3} \vee \overline{x_{4}}\right) \\
x_{3} \text { is a }(2,1) \text {-literal, } \operatorname{deg}\left(x_{3}\right)=3 .
\end{gathered}
$$

## Preliminaries

If we assign value 1 to literal $x(x=1, \bar{x}=0)$, then

- All clauses containing literal $x$ will be removed from the formula.
- All literals $\bar{x}$ will be removed from the clauses.

We use $\mathcal{F}_{x=1}$ to indicate the formula after assigning $x=1$.

$$
\begin{gathered}
\mathcal{F}=\left(x_{1} \vee x_{2} \vee \overline{x_{3}}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{3} \vee x_{4}\right) \wedge\left(\overline{x_{1}} \vee x_{3} \vee \overline{x_{4}}\right) \\
\mathcal{F}_{x_{3}=1}=\left(x_{1} \vee x_{2}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right)
\end{gathered}
$$

## Reduction Rules

R-Rule 1 (Elimination of duplicated literals). If a clause $C$ contains duplicated literals $z$, remove all but one $z$ in $C . \mathcal{F}^{\prime} \wedge(z z D) \rightarrow \mathcal{F}^{\prime} \wedge(z D)$.

R-Rule 2 (Elimination of subsumptions). If there are two clauses $C$ and $D$ such that $C \subseteq D$, remove clause $D . \mathcal{F}^{\prime} \wedge C \wedge D \rightarrow \mathcal{F}^{\prime} \wedge C$.

R-Rule 3 (Elimination of tautology). If a clause $C$ contains two opposite literals $z$ and $\bar{z}$, remove clause $C . \mathcal{F}^{\prime} \wedge(z \bar{z} C) \wedge D \rightarrow \mathcal{F}^{\prime} \wedge D$.

R-Rule 4 (Elimination of 1-clauses and pure literals). If there is a 1-clause $\{x\}$ or a $\left(1^{+}, 0\right)$-literal $x$, assign $x=1$. $\mathcal{F}^{\prime} \wedge(x) \rightarrow \mathcal{F}_{x=1}^{\prime}$.

And some other reduction rules... (R-Rule $6 \sim$ R-Rule 10)
A CNF-formula is called reduced, if none of reduction rules can be applied on it.

## Reduction Rules

## Lemma

In a reduced CNF-formula $\mathcal{F}$, all variables are $3^{+}$-variables.

## Lemma

In a reduced CNF-formula $\mathcal{F}$, if there is a 2-clause $x y$, then no other clause in $\mathcal{F}$ contains $x y, \bar{x} y$, or $x \bar{y}$.

And some other properties...

## Our Algorithm

For a literal $x$, we have two kinds of branching:

- simple branching: $x=1$ and $x=0$
- strong branching: $x=1 \& C=0$ and $x=0$, where $x$ is a $(1, i)$-literal and $x C$ is the only clause containing literal $x$.

## Our Algorithm

## Algorithm 1: $\operatorname{SAT}(\mathcal{F})$

Input: a CNF-formula $\mathcal{F}$
Output: 1 or 0 to indicate the satisfiability of $\mathcal{F}$
Step 1. If $\mathcal{F}=\emptyset$, return 1. If $\mathcal{F}$ contains an empty clause, return 0.
Step 2. If $\mathcal{F}$ is not a reduced CNF-formula, iteratively apply the reduction rules to reduce it.
Step 3. If there is a $d$-variable $x$ with $d \geq 6$, return $\operatorname{SAT}\left(\mathcal{F}_{x=1}\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 4. If there is a $(1,4)$-literal $x$ (assume $x C$ is the only clause containing $x)$, return $\operatorname{SAT}\left(\mathcal{F}_{x=1} \& C=0\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 5. If there is a 5 -variable $x$ contained in a 2 -clause, return $\operatorname{SAT}\left(\mathcal{F}_{x=1}\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 6. If there is a 5 -variable $x$ contained in a $4^{+}$-clause, return $\operatorname{SAT}\left(\mathcal{F}_{x=1}\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 7. If there is a clause containing both a 5 -variable $x$ and a $4^{-}$-variable, return $\operatorname{SAT}\left(\mathcal{F}_{x=1}\right) \operatorname{VAT}\left(\mathcal{F}_{x=0}\right)$.
Step 8. If there are still some 5 -variables, then $\mathcal{F}=\mathcal{F}^{*} \wedge \mathcal{F}^{\prime}$, where $\mathcal{F}^{*}$ is a 3-CNF with $\operatorname{var}\left(\mathcal{F}^{*}\right)$ be the set of 5 -variables in $\mathcal{F}$ and $\operatorname{var}\left(\mathcal{F}^{*}\right) \cap \operatorname{var}\left(\mathcal{F}^{\prime}\right)=\emptyset$. We return $\operatorname{SAT}\left(\mathcal{F}^{*}\right) \wedge \operatorname{SAT}\left(\mathcal{F}^{\prime}\right)$ and solve $\mathcal{F}^{*}$ by using the 3-SAT algorithm by Liu [14].
Step 9. If there is a $(1,3)$-literal $x$ (assume $x C$ is the only clause containing $x)$, return $\operatorname{SAT}\left(\mathcal{F}_{x=1} \& C=0\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 10. If there is a $(2,2)$-literal $x$, return $\operatorname{SAT}\left(\mathcal{F}_{x=1}\right) \vee \operatorname{SAT}\left(\mathcal{F}_{x=0}\right)$.
Step 11. Apply the algorithm by Wahlström [18] to solve the instance.

Step 11. Apply the algorithm by Wahlström [18] to solve the instance.

## Chen and Liu's algorithm ${ }^{6}$ in 2009

${ }^{6}$ Chen, J., Liu, Y.: An improved SAT algorithm in terms of formula length. (WADS2009)

## Running Time Bound Analysis

To determine the worst-case running time of a branching algorithm, we can analyze the size of the search tree generated in the algorithm.

- First a measure $\mu$ is defined.
- We use $T(\mu)$ to indicate the maximum size or the number of leaves of the search tree for the input with the measure being at most $\mu$.
- If the algorithm branches into / sub-branches with the measure decreasing at least $a_{i}$ in the $i$-th sub-branch, we get a recurrence relation: $T(\mu) \leq T\left(\mu-a_{1}\right)+T\left(\mu-a_{2}\right)+\cdots+T\left(\mu-a_{l}\right)$.

## Running Time Bound Analysis

- If the algorithm branches into / sub-branches
 with the measure decreasing at least $a_{i}$ in the $i$-th sub-branch, we get a recurrence relation: $T(\mu) \leq T\left(\mu-a_{1}\right)+T\left(\mu-a_{2}\right)+\cdots+T\left(\mu-a_{l}\right)$.
- $\left[a_{1}, a_{2}, \ldots, a_{l}\right]$ is called a branching vector.
- The largest root of the function $f(x)=1-\sum_{i=1}^{l} x^{-a_{i}}$ is called the branching factor of the recurrence.
- $T(\mu)=O\left(\gamma^{\mu}\right)$, where $\gamma$ is the maximum branching factor of all branching factors.

## Running Time Bound Analysis

- If the algorithm branches into / sub-branches
 with the measure decreasing at least $a_{i}$ in the $i$-th sub-branch, we get a recurrence relation: $T(\mu) \leq T\left(\mu-a_{1}\right)+T\left(\mu-a_{2}\right)+\cdots+T\left(\mu-a_{l}\right)$.
- $\left[a_{1}, a_{2}, \ldots, a_{l}\right]$ is called a branching vector.
- The largest root of the function $f(x)=1-\sum_{i=1}^{l} x^{-a_{i}}$ is called the branching factor of the recurrence.
- $T(\mu)=O\left(\gamma^{\mu}\right)$, where $\gamma$ is the maximum branching factor of all branching factors.
- Running time bound: $O^{*}\left(\gamma^{\mu}\right)$.

## Measure and Conquer

The main idea is to adopt a new measure instead of measure $L$.

## Measure and Conquer

The main idea is to adopt a new measure instead of measure $L$.
We introduce a weight to each variable in the formula according to the degree of the variable:

$$
w: \mathbb{Z}^{+} \rightarrow \mathbb{R}^{+}
$$

$w_{i}$ denote the weight of a variable with degree $i$.

## Measure and Conquer

The main idea is to adopt a new measure instead of measure $L$.
We introduce a weight to each variable in the formula according to the degree of the variable:

$$
w: \mathbb{Z}^{+} \rightarrow \mathbb{R}^{+}
$$

$w_{i}$ denote the weight of a variable with degree $i$.
In our algorithm, the measure $\mu$ of a formula $\mathcal{F}$ is defined as:

$$
\mu(\mathcal{F})=\sum_{x \in \mathcal{F}} w_{\operatorname{deg}(x)}
$$

## Measure and Conquer

The main idea is to adopt a new measure instead of measure $L$.
We introduce a weight to each variable in the formula according to the degree of the variable:

$$
w: \mathbb{Z}^{+} \rightarrow \mathbb{R}^{+}
$$

$w_{i}$ denote the weight of a variable with degree $i$.
In our algorithm, the measure $\mu$ of a formula $\mathcal{F}$ is defined as:

$$
\mu(\mathcal{F})=\sum_{x \in \mathcal{F}} w_{\operatorname{deg}(x)}
$$

Let $n_{i}$ denote the number of $i$-variables in $\mathcal{F}$. We also have

$$
\mu(\mathcal{F})=\sum_{i} n_{i} \cdot w_{i}
$$

## Measure and Conquer

If we ensure that $w_{i} \leq i$, then we have

$$
\mu(\mathcal{F})=\sum_{i} n_{i} \cdot w_{i} \leq \sum_{i} n_{i} \cdot i \leq L(\mathcal{F})
$$

This tells us if we get a running time bound of $O^{*}\left(c^{\mu(\mathcal{F})}\right)$ for a real number $c$, we also get a running time bound of $O^{*}\left(c^{L(\mathcal{F})}\right)$.

## Measure and Conquer

We also define $\delta_{i}=w_{i}-w_{i-1}$, this is roughly the weight of a literal with its corresponding variable have a degree of $i$.

For each branching rule, we will analyze how much the new measure $\mu(\mathcal{F})$ decreases in each sub-branch to get the running time bound.

An example:

$$
\begin{gathered}
\mathcal{F}=\left(x_{1} \vee x_{2} \vee \overline{x_{3}}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{3} \vee x_{4}\right) \wedge\left(\overline{x_{1}} \vee x_{3} \vee \overline{x_{4}}\right) \\
\mathcal{F}_{x_{3}}=1=\left(x_{1} \vee x_{2}\right) \wedge\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \\
\mathcal{F}_{x_{3}}=0=\left(\overline{x_{2}} \vee \overline{x_{4}}\right) \wedge\left(x_{4}\right) \wedge\left(\overline{x_{1}} \vee \overline{x_{4}}\right)
\end{gathered}
$$

The branching vector is:

$$
\left[\left(w_{3}\right)+\left(\delta_{2}\right)+\left(\delta_{3}+\delta_{2}\right),\left(w_{3}\right)+\left(\delta_{2}\right)+\left(\delta_{2}\right)\right]
$$

## Measure and Conquer

How does the new measure work? Consider two cases when the maximum degree is 4 .

## Measure and Conquer

How does the new measure work? Consider two cases when the maximum degree is 4 .

Adopt $L$ as the measure
$w_{4}=4, w_{3}=3 \Rightarrow \delta_{4}=1:$

$$
\begin{array}{c|c}
\text { Branching vector } & \text { Branching factor } \\
{\left[w_{4}+2 w_{3}, w_{4}+6 \delta_{4}\right]} & 1.0718 \\
{\left[w_{4}+2 \delta_{4}, w_{4}+6 \delta_{4}\right]} & 1.0926
\end{array}
$$

## Measure and Conquer

Adopt $\mu$ as the measure

If we set $w_{5}=5, w_{4}=3.84682, w_{3}=1.92341 \Rightarrow \delta_{4}=1.92341$ :

$$
\begin{array}{c|c}
\text { Branching vector } & \text { Branching factor } \\
{\left[w_{4}+2 w_{3}, w_{4}+6 \delta_{4}\right]} & 1.0646 \\
{\left[w_{4}+2 \delta_{4}, w_{4}+6 \delta_{4}\right]} & 1.0646
\end{array}
$$

## Running Time Bound Analysis

Assumptions:

- $w_{1}=w_{2}=0$
- $w_{i} \leq i(3 \leq i \leq 4), w_{4}=2 w_{3}$
- $w_{i}=i(i \geq 5)$
- $\delta_{i}>0(i \geq 3)$
- ...

In Step 8, the literals of all 5-variables form a 3-SAT instance $\mathcal{F}^{*}$. We apply the $O^{*}\left(1.3279^{n}\right)$-time algorithm for 3-SAT to solve our problem, where $n$ is the number of variables in the instance. Since $w_{5}=5$, we have that $n=\mu\left(\mathcal{F}^{*}\right) / w_{5}=\mu\left(\mathcal{F}^{*}\right) / 5$. So the running time for this part will be

$$
O^{*}\left(1.3279^{\mu\left(\mathcal{F}^{*}\right) / w_{5}}\right)=O^{*}\left(1.0584^{\mu\left(\mathcal{F}^{*}\right)}\right)
$$

## Running Time Bound Analysis

In Step 11, all variables are 3-variables. We apply the $O^{*}\left(1.1279^{n}\right)$-time algorithm by Wahlström to solve this special case, where $n$ is the number of variables. For this case, we have that $n=\mu(\mathcal{F}) / w_{3}$. So the running time of this part is

$$
O^{*}\left(\left(1.1279^{1 / w_{3}}\right)^{\mu(\mathcal{F})}\right)
$$

## The Final Result

Table 2. The weight setting

| $w_{1}=w_{2}=0$ |  |
| :--- | :--- |
| $w_{3}=1.9234132344759123$ | $\delta_{3}=1.9234132344759123$ |
| $w_{4}=3.8468264689518246$ | $\delta_{4}=1.9234132344759123$ |
| $w_{5}=5$ | $\delta_{5}=1.1531735310481754$ |
| $w_{i}=i(i \geq 6)$ | $\delta_{i}=1(i \geq 6)$ |

Table 3. The branching vector and factor for each step

| Steps | Branching vectors | Branching factors |
| :--- | :---: | :---: |
| Step 3 | $\left[w_{6}+\delta_{6}, w_{6}+11 \delta_{6}\right]$ | 1.0636 |
| Step 4 | $\left[w_{5}+2 w_{3}, w_{5}+8 \delta_{5}\right]$ | 1.0632 |
| Step 5 | $\left[w_{5}+3 \delta_{5}, w_{5}+2 w_{3}+5 \delta_{5}\right]$ | 1.0618 |
| Step 6 | $\left[w_{5}+2 \delta_{5}, w_{5}+4 w_{3}+4 \delta_{5}\right]$ | 1.0636 |
| Step 7 | $\left[w_{5}+4 \delta_{5}, w_{5}+5 \delta_{5}\right]$ | 1.0636 |
| Step 8 | $O^{*}\left(\left(1.3279^{1 / w_{5}}\right)^{\mu}\right)$ | 1.0646 |
| Step 9 | $\left[w_{4}+2 w_{3}, w_{4}+6 \delta_{4}\right]$ | 1.0584 |
| Step 10 | $\left[w_{4}+2 \delta_{4}, w_{4}+6 \delta_{4}\right]$ | 1.0646 |
| Step 11 | $O^{*}\left(\left(1.1279^{1 / w_{3}}\right)^{\mu}\right)$ | 1.0646 |

The best choice of $w_{i}$ can be found by solving a quasi-convex program problem.

## The Final Result
